Life Agent

Whoop Connection Guide

This guide walks you through connecting your Whoop account to Life Agent — what it unlocks, how the login actually works under the hood, and how to troubleshoot it when something goes wrong.

Estimated setup time: 5 minutes • Requires a Whoop device + active membership

0. What This Unlocks

Life Agent is fully usable without Whoop — goals, calendar, journal and the board all work without it. Connecting Whoop adds your real recovery data into four places:

Where	What it adds
Morning briefing	Recovery %, HRV, resting heart rate, 14-day recovery/sleep trend, training load, an overtraining warning
Sport board agent	Live recovery score woven into its advice when you ask the board a training question
Planning agent	Recovery-aware day/week plans — dagplan and weekplan adjust training suggestions to how recovered you are
Weekly review	7-day recovery, sleep and training summary in the AI-generated week analysis

Everything below happens between your machine and Whoop's servers directly — no third party sees your data, and nothing is uploaded anywhere except to Claude for generating the text advice.

1. How the Login Works (in plain terms)

Life Agent never sees or asks for your Whoop password. Instead it uses OAuth2, the same mechanism as "Sign in with Google":

- You run `python cli.py whoop-login`.
- The script starts a tiny, temporary web server on your own machine (localhost:8080) and opens your browser to Whoop's real login page.
- You log in on Whoop's own site and click Authorize — your password never touches Life Agent.
- Whoop redirects your browser back to that local server with a one-time authorization code.
- The script trades that code for an access token + refresh token, and saves them to a local file.

- Every future command reads that file — you don't log in again.

This is why the redirect URI has to point at localhost:8080 — that's the address of the temporary local server catching Whoop's redirect.

2. Create a Whoop Developer App

1. Go to developer.whoop.com and sign in with your normal Whoop account.
2. Create a new app (any name, e.g. "Life Agent").
3. In the app settings, set the **Redirect URI** to exactly:

```
http://localhost:8080/callback
```

This must match character-for-character — Whoop rejects the login if it doesn't. Don't change the port (8080): the local script that catches the login always listens there.

4. Under scopes, enable at least the six the code actually requests:

Scope	Why Life Agent needs it
`offline`	Issues a refresh token so you only log in once, ever
`read:recovery`	Recovery %, HRV, resting heart rate
`read:sleep`	Sleep performance % and sleep stages
`read:cycles`	Daily strain / today's physiological cycle
`read:workout`	Workout history for the training-load summary
`read:body_measurement`	Height/weight/max HR, used for some calculations

Skipping a scope doesn't break anything — the affected section just won't have data. If you'd rather not share body measurements, for example, leave that scope out.

5. Save the app. You'll see a **Client ID** and **Client Secret** — treat the secret like a password, copy both, you'll need them next.

3. Add Credentials to .env

Open `.env` in the life-agent folder (copy it from `.env.example` first if you haven't already) and fill in:

```
WHOOP_CLIENT_ID=your-client-id WHOOP_CLIENT_SECRET=your-client-secret
WHOOP_REDIRECT_URI=http://localhost:8080/callback
```

The redirect URI here must be identical to the one you registered in section 2.

4. Log In

From the life-agent folder, run:

```
python cli.py whoop-login
```

A browser window opens asking you to log in to Whoop and authorize the app. Approve it — the tab will show "Login gelukt! Sluit dit venster." and you can close it.

Behind the scenes, a token is saved to `.whoop_token.json` in the life-agent folder. It refreshes itself automatically from then on — you only do this once.

5. Verify It Works

Test the pieces one at a time so a problem is easy to isolate:

```
python cli.py status # recovery + agenda, fastest check python
morning_briefing.py # full briefing, recovery section at the top python
board.py sport "How should I train today?" # sport agent using recovery
```

You should see your recovery score, HRV and resting heart rate. If Whoop's servers haven't closed your current cycle yet, recovery can briefly show as unavailable — that's normal, it resolves after your next sleep.

6. Token Lifecycle & Security

How refreshing works — the script doesn't track when your token expires. Every API call just tries the saved access token first; if Whoop responds "401 Unauthorized", it silently uses the refresh token to get a new one and retries. You never see this happen.

Where it's stored — plain JSON at `.whoop_token.json` in the life-agent folder, containing your access and refresh token. Anyone with that file can read your Whoop data until you revoke access.

Keep it out of git

This file is not a secret you type in — it's generated locally after login. Make sure your project's `.gitignore` includes it before you ever commit:

```
.whoop_token.json
```

If it ever does end up in a commit or a shared zip, treat the token as leaked: revoke the app's access from your Whoop account settings and log in again to generate a fresh one.

Revoking access — you can disconnect Life Agent at any time from your Whoop account's connected-apps settings, without touching your Whoop membership itself. The local token file becomes useless immediately; delete it and run `whoop-login` again if you reconnect later.

7. Optional — CSV History Fallback

For trend analysis (recovery/sleep trends over 14 days, overtraining signal), the system can also read Whoop's exported CSV history instead of the live API.

1. In the Whoop app: Settings → Data Export → request your export (you'll get an email with a download link).
2. Place these three files in the folder that **contains** your life-agent folder (one level up, next to it — not inside it):

```
physiological_cycles.csv sleeps.csv workouts.csv
```

This step is optional — the live API path in sections 2-5 is what powers the daily briefing. The CSVs only add historical trend context.

8. Troubleshooting

"redirect_uri mismatch" error

The URI in .env doesn't exactly match the one registered on developer.whoop.com. Check for a trailing slash, http vs https, or a typo — they must be identical, character for character.

Browser doesn't open / login hangs forever

Make sure nothing else is using port 8080 on your machine (another dev server, a previous stuck run) — the local callback server can't bind if it's taken. Close whatever's on that port, then run python cli.py whoop-login again.

"Geen autorisatiecode ontvangen van Whoop"

You closed the browser tab before approving, denied access, or the redirect landed somewhere it couldn't be caught. Run the login command again and click Authorize before closing the tab.

401 / token errors after it worked before

The token normally refreshes itself on any 401. If it's genuinely stuck (e.g. you revoked access on Whoop's side), delete .whoop_token.json and run python cli.py whoop-login again.

No recovery data / empty section

Your most recent sleep cycle may still be open — Whoop typically closes it a few hours after you wake up. It resolves on its own, or use the CSV fallback for older data in the meantime.

Client Secret rejected / invalid_client error

Double-check you copied the Secret, not the Client ID, into WHOOP_CLIENT_SECRET, and that there's no stray space or quote character pasted in from the developer portal.

Works on one machine, not on another

The token file is local — it doesn't travel with the code. Run python cli.py whoop-login once on each machine you use.

9. FAQ

Do I need a paid Whoop membership?

Yes — the API reflects your live Whoop account, so it needs an active membership the same way the Whoop app does.

Does this affect my Whoop device or app?

No. It only reads data Whoop already collected; nothing is written back, and your phone app keeps working exactly as before.

Do I have to log in every day?

No. The offline scope gives Life Agent a refresh token, so one login lasts until you revoke access or delete the token file.

What if I don't want to connect Whoop at all?

Skip this guide entirely. Recovery sections will just show "No data available" and every other feature — goals, calendar, journal, board — works normally without it.

Is my data sent anywhere besides Whoop and my own machine?

The raw numbers stay local. Only when a feature generates AI text (e.g. the 3 focus points or the sport agent's advice) does a short summary of that data get sent to Claude to generate the response.

This is a supplement to the main Installation Guide — see that document for the rest of the setup (Anthropic API key, goals, calendar).
